

The creation of this web application was easy to start off with, I already knew what models I needed to have and the fields I needed to create because I created the same API in studio 3. Things started getting difficult once I started creating the front-end, most of the stuff I needed to do was inside of all the lecture notes but, stuff like logging out was not, trying to figure that out was very difficult, I had to think of how I was going to get rid of the token that was provided once a user was logged in. Some other challenges was Role Based actions, trying to implement that into the front-end became difficult, I had to think of things such as, what should a certain role be able to do, what should they not be able to do, how do I render elements on the website based on a users role. I encountered conflicts when fetching users and also fetching the user that was logged in, this was because I was fetching users with variable defined as "users", and fetching the logged in user details as "user", I solved this simply by just renaming the logged in user details to "loggedInUser". This solved a lot of problems I had and made rendering elements and other things based on the user's role.

What I would do differently next time is, spend more time thinking about the little things, a lot more testing, also trying to maximize my time management, I focused on this project and class a lot more than any other subject. Some new skills I picked up during the creation of this website is, creating RESTful API's, I already how to fetch someone else's API but now I know how to create one, some more skills I learned were, deploying a web application both front and back end, this comes with some challenges of its own because I had to find what environment variables need to go where.
